Speedy Performance Estimation via Learning Curve Extrapolation

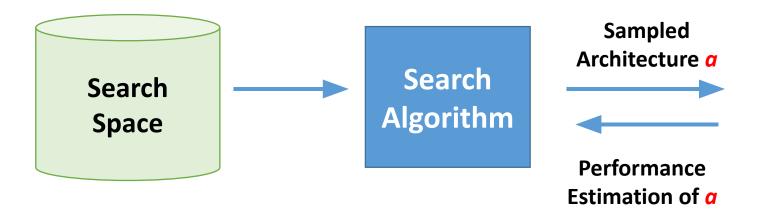

- Create a Multi-Fidelity Surrogate Benchmark for Evaluating Anytime NAS algorithms
- Speedy Estimations via Partial Curve Extrapolations

Neural Architecture Search (NAS)

Architectures found by NAS

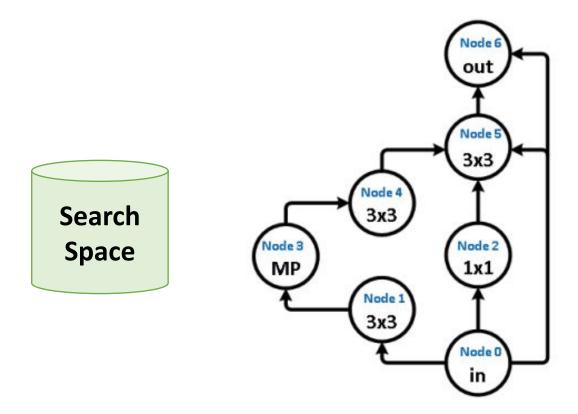

Neural Architecture Search (NAS) Pipeline

Performance Estimation Strategy

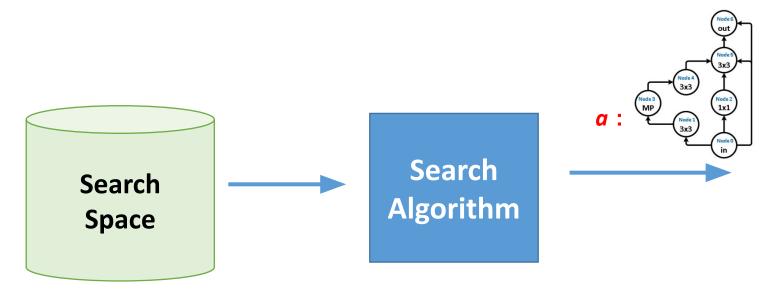

Search Space

Set of Operations:

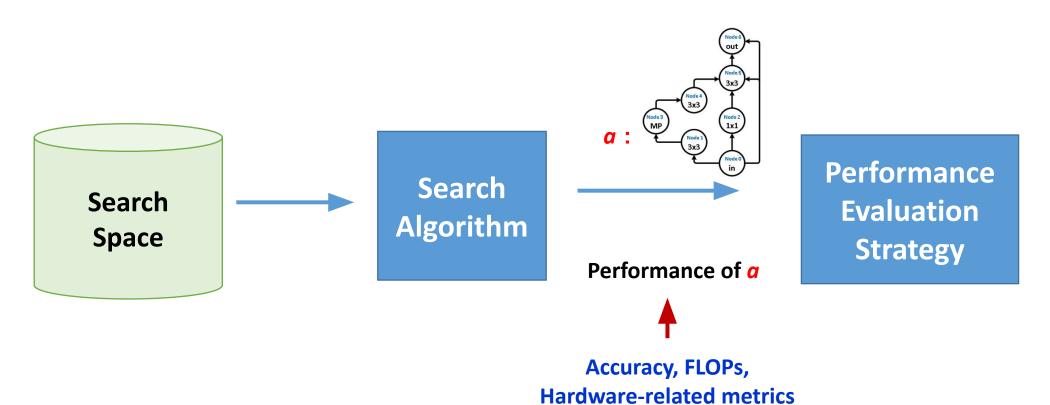

- Identity
- 3x3 convolution
- 1x1 convolution
- 3x3 max pooling
- skip connection

Search Algorithm + Performance Evaluation

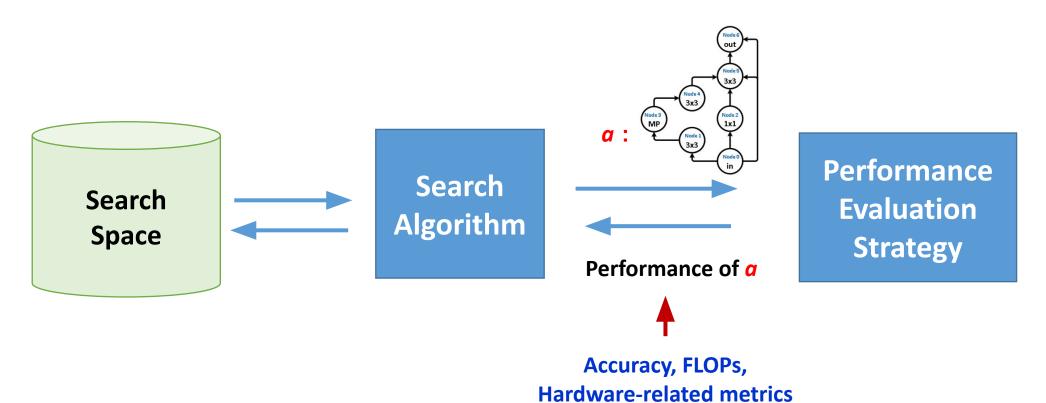

e.g. Random Search, Evolution, Reinforcement Learning, Bayesian Optimization, One-shot (supernet)

Search Algorithm + Performance Evaluation

e.g., latency, power consumption

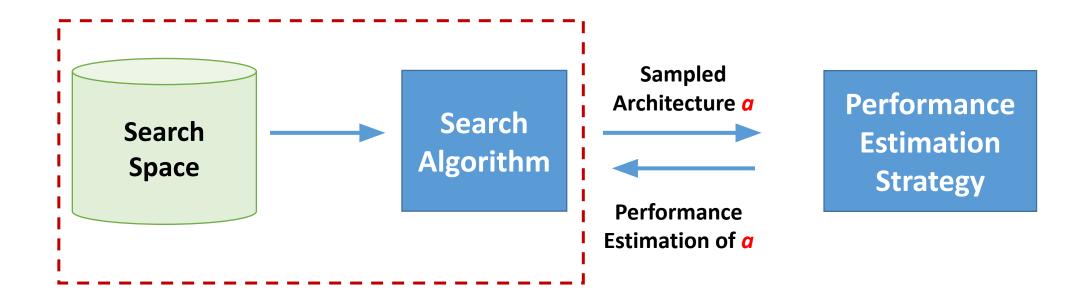

Search Algorithm + Performance Evaluation

e.g., latency, power consumption

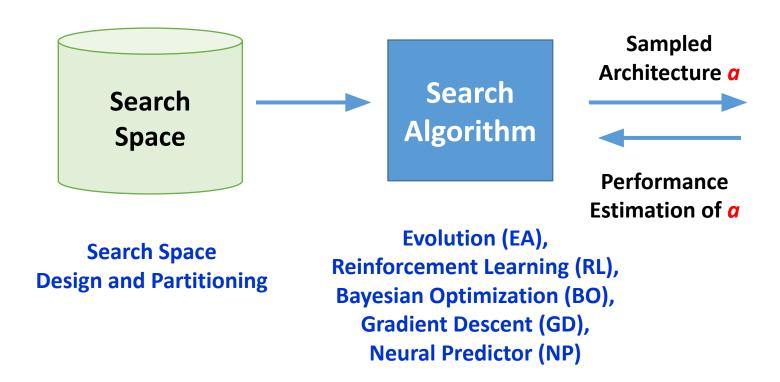

8

Recall this Figure

- Supernet-based training optimizes search space and search algorithm together
- The optimization of the architecture representations are guided by the accuracies of architectures selected by the search strategies
- What if the accuracies are bad at the beginning (e.g. cool-start)?

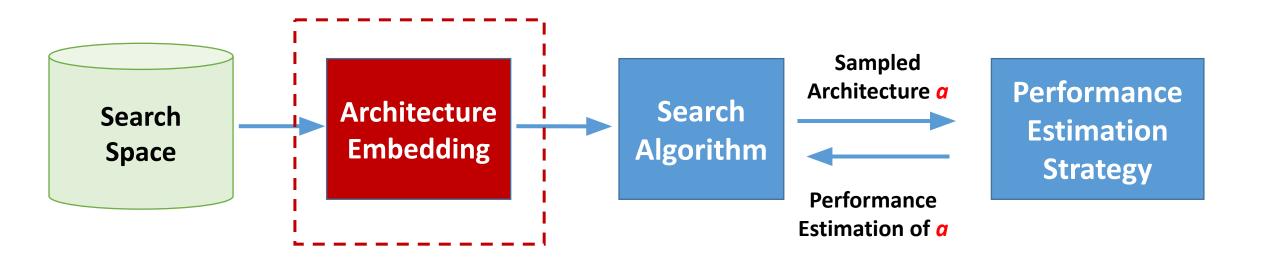

From the Classic NAS Framework

Performance Estimation Strategy

Weight Sharing,
Lower Fidelity Estimates,
Bandit-based,
Learning Curve Extrapolation

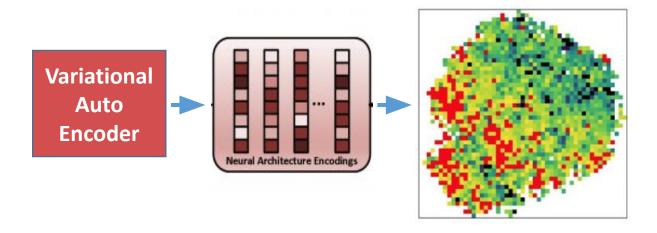

To a Study on Architecture Embeddings

In the following, I talk about our research on decoupling neural network representation learning and its downstream search, as well as the effect of architecture representations on the overall performance of NAS.

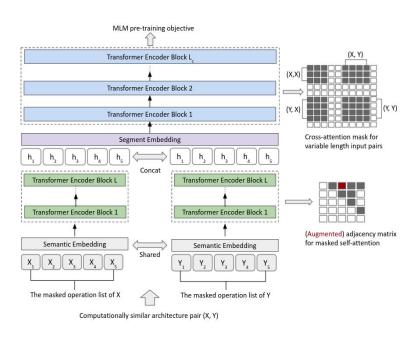

arch2vec and CATE

arch2vec [NeurIPS' 20]

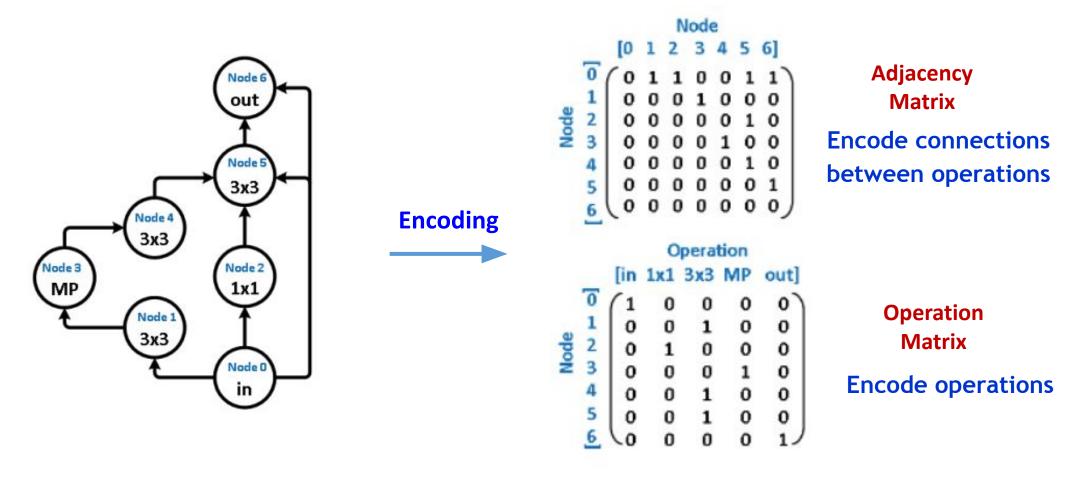

arch2vec is a structure-aware unsupervised learning-based architecture encoding method that **decouples** architecture representation learning and architecture search into two separate processes.

CATE [ICML' 21]

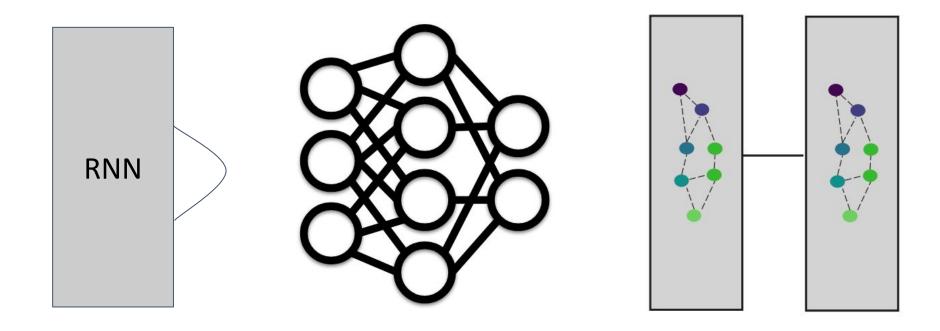

CATE is a computation-aware architecture encoding method that encodes **computations** instead of structures of neural architectures via a transformer-based encoder.

Recap: Adjacency Matrix-based Encoding

The size of the adjacency matrix grows **quadratically** as search space scales up, making the downstream architecture search **much less efficient**.

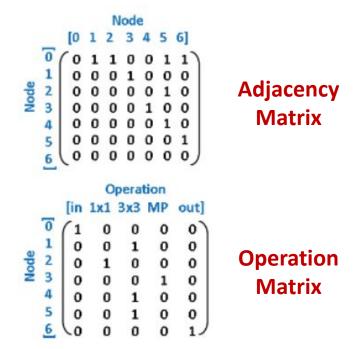

Recap: Learning-based Embeddings

Different Types of Architecture Encoders such as LSTM, MLP, and GCN

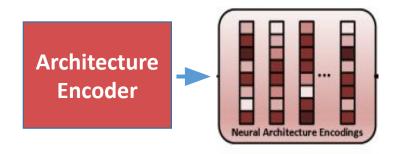

Why Learning-based Embeddings

Adjacency Matrix-based Encoding

High-dimensional & discrete search space

Learning-based Embeddings

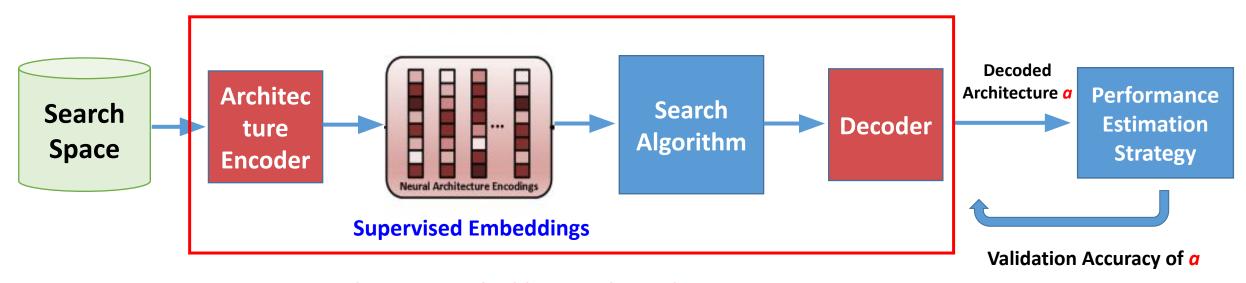

Learned architecture embeddings in the Low-dimensional latent space

Conducting neural architecture search on such low-dimensional continuous space is much easier and is hence more efficient.

Drawback of Existing Learning-based Embedding Methods

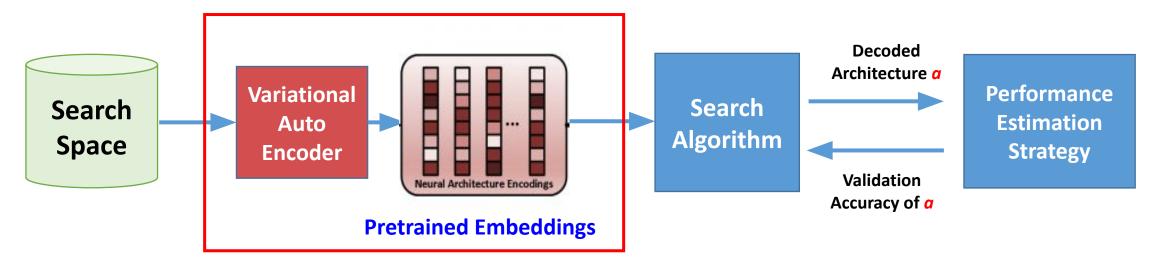

• Architecture embeddings and search algorithms are **jointly** optimized in a **supervised** manner, guided by the accuracies of architectures selected by the search strategies.

Architecture embeddings and search strategies are jointly optimized in a supervised manner

Our Proposed Method: arch2vec

- We propose arch2vec, a simple yet effective unsupervised architecture representation learning method for neural architecture search.
- **Decouple** architecture embedding learning and architecture search into two **separate** processes.

Pre-training architecture embeddings in an unsupervised manner

Variational Graph Isomorphism Autoencoder

Let A denote Adjacency Matrix, X denote Operation Matrix.

Augment A as $\tilde{A} = A + A^T$ to transfer original directed graph into undirected one to allow bi-directional information flow.

Encoder

$$q(\mathbf{Z}|\mathbf{X}, \mathbf{\tilde{A}}) = \prod_{i=1}^{N} q(\mathbf{z}_i|\mathbf{X}, \mathbf{\tilde{A}}), ext{with } q(\mathbf{z}_i|\mathbf{X}, \mathbf{\tilde{A}}) = \mathcal{N}(\mathbf{z}_i|\boldsymbol{\mu}_i, diag(\boldsymbol{\sigma}_i^2)),$$

$$\mathbf{H}^{(k)} = \mathrm{MLP}^{(k)} \left(\left(1 + \epsilon^{(k)} \right) \cdot \mathbf{H}^{(k-1)} + \tilde{\mathbf{A}} \mathbf{H}^{(k-1)} \right), k = 1, 2, \dots, L$$

L-layer Graph Isomorphism Network (GIN)

Decoder

$$p(\hat{\mathbf{A}}|\mathbf{Z}) = \prod_{i=1}^{N} \prod_{j=1}^{N} P(\hat{A}_{ij}|\mathbf{z}_i, \mathbf{z}_j), \text{ with } p(\hat{A}_{ij} = 1|\mathbf{z}_i, \mathbf{z}_j) = \sigma(\mathbf{z}_i^T \mathbf{z}_j)$$

Reconstructed Adjacency Matrix

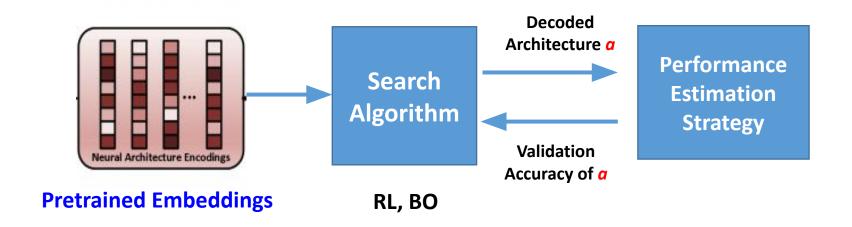

$$p(\hat{\mathbf{X}} = [k_1, ..., k_N]^T | \mathbf{Z}) = \prod_{i=1}^N P(\hat{\mathbf{X}}_i = k_i | \mathbf{z}_i) = \prod_{i=1}^N \operatorname{softmax}(\mathbf{W}_o \mathbf{Z} + \mathbf{b}_o)_{i, k_i}$$
Reconstructed Operation Matrix

Training objective

$$\mathcal{L} = \mathbb{E}_{q(\mathbf{Z}|\mathbf{X}, \mathbf{ ilde{A}})}[\log p(\hat{\mathbf{X}}, \hat{\mathbf{A}}|\mathbf{Z})] - \mathcal{D}_{\mathit{KL}}(q(\mathbf{Z}|\mathbf{X}, \mathbf{ ilde{A}})||p(\mathbf{Z}))$$

Pretrained Embeddings for Architecture Search

We use reinforcement learning (RL) and Bayesian optimization (BO) as two representative search algorithms.

- RL: State: pretrained embeddings. Policy Net: LSTM. Reward: Validation accuracy
- BO: Surrogate: 2-Layer MLP (instead of GP). Acquisition function: El.
- Output top-K architectures in each round of search and optimize the policy/surrogate iteratively

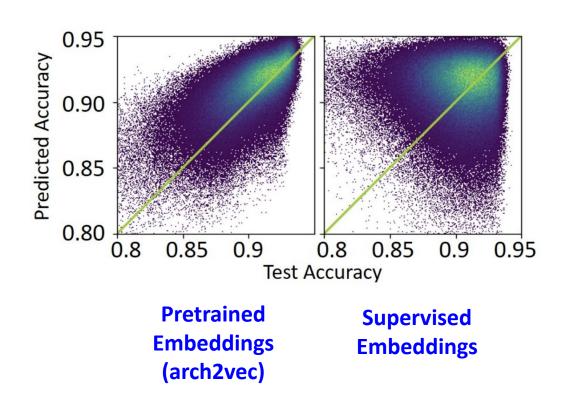

Pre-training Performance

- Three commonly used NAS search spaces: **NAS-Bench-101**, **NAS-Bench-201**, and the **DARTS** search space.
- We compare *arch2vec* with two baselines: Graph Autoencoders (GAE) and Variational Graph Autoencoders (VGAE) under three metrics:
 - Reconstruction Accuracy: how accurate the reconstructed network architectures are.
 - Validity: how often the generated architectures are valid graphs.
 - Uniqueness: how many generated valid architectures are unique.

	Method	NAS-Bench-101			NAS-Bench-201			DARTS		
	Method	Accuracy	Validity	Uniqueness	Accuracy	Validity	Uniqueness	Accuracy	Validity	Uniqueness
•	GAE [27]	98.75	29.88	99.25	99.52	79.28	78.42	97.80	15.25	99.65
\ \frac{1}{2}	VGAE [27]	97.45	41.18	99.34	98.32	79.30	88.42	96.80	25.25	99.27
7.	arch2vec	100	51.33	99.36	100	79.41	98.72	99.79	33.36	100

Understanding Pre-trained Embeddings (1)

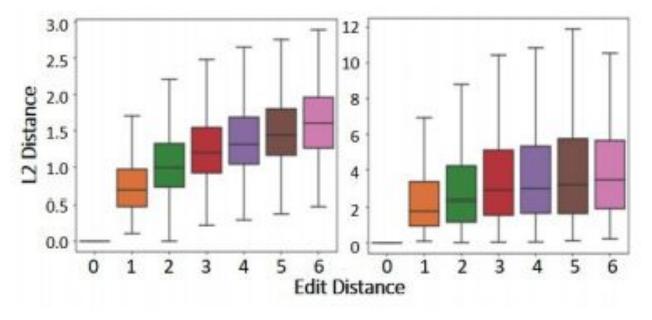

- We compare the predictive performance of the pretrained embeddings and supervised embeddings. This metric measures how well the embeddings can predict the performance of the corresponding architectures.
- We train a Gaussian Process model with 250 sampled data to predict all data and report the results across 10 different seeds. We use RMSE and the Pearson correlation coefficient to evaluate points with test accuracy larger than 0.8.

The RMSE and Pearson's r are: $0.038\pm0.025 / 0.53\pm0.09$ for supervised embeddings, and $0.018\pm0.001 / 0.67$ ±0.02 for arch2vec.

Understanding Pre-trained Embeddings (2)

- We compare the distribution of L2 distance between architecture pairs by edit distance, measured by 1,000 architectures sampled in a long random walk with 1 edit distance apart from consecutive samples.
- The L2 distance of pretrained embeddings grows monotonically with increasing edit distance.
- This statistic indicates that the pretrained embeddings are able to better preserve the structural information of input space, and thus make similar architectures clustered better.

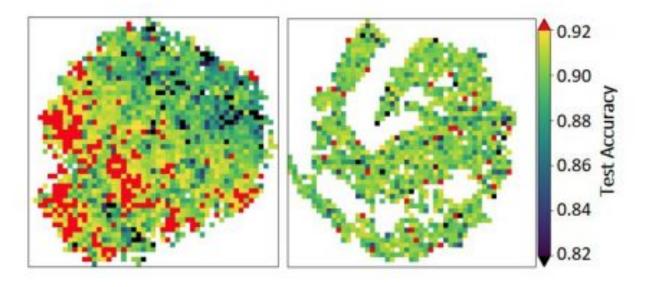

Pretrained Embeddings (arch2vec)

Supervised Embeddings

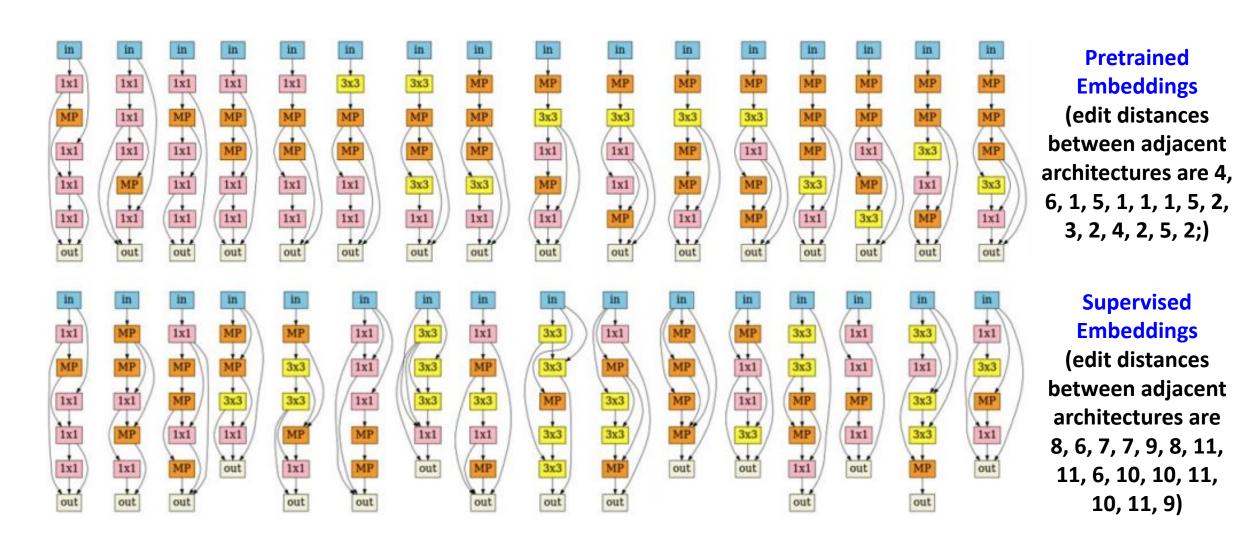

Understanding Pre-trained Embeddings (3)

- We visualize the latent spaces learned by arch2vec and its supervised learning counterpart in 2-dimensional space.
- Compared to supervised embeddings, pretrained embeddings span the whole latent space, and architectures with similar accuracies are clustered and distributed more smoothly in the latent space.
- Conducting architecture search on such smooth performance surface is much easier and is hence more efficient.

Latent space 2D visualization comparison between arch2vec (left) and supervised architecture representation learning (right). Color encodes test accuracy.

Understanding Pre-trained Embeddings (4)

Understanding Pre-trained Embeddings (4)

- The peak has a coarse-grained width of about 6
 - It means for joint optimization, the RWA is nearly 0

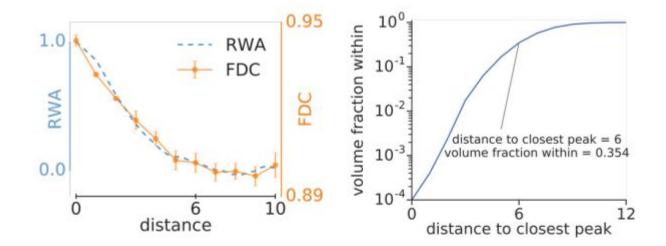

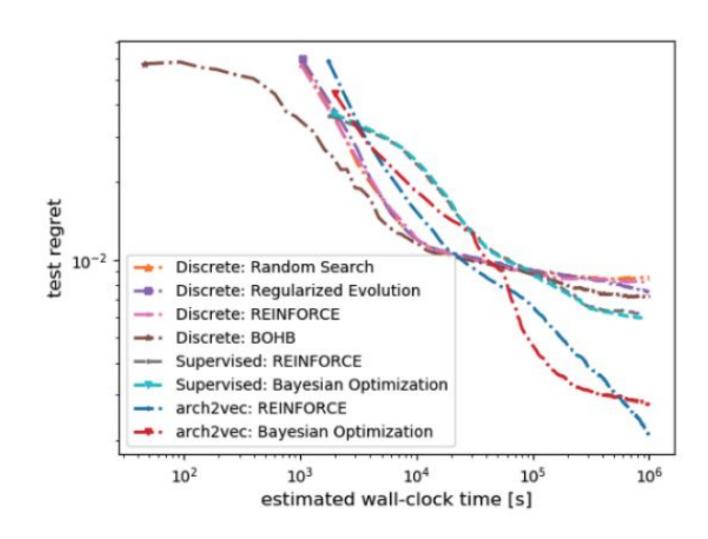

Figure 6: (left) RWA for the full space and the FDC relative to the global maximum. To plot both curves on a common horizontal axis, the autocorrelation curve is drawn as a function of the square root of the autocorrelation shift, to account for the fact that a random walk reaches a mean distance \sqrt{N} after N steps. (right) Fraction of the search space volume that lies within a given distance to the closest high peak.

Architecture Search Performance on NAS-Bench-101

- BOHB and RE are two best-performing search methods using discrete encoding.
- However, they perform slightly worse than supervised architecture representation learning.
- arch2vec considerably outperforms its supervised counterpart and the discrete encoding after 50,000 wall clock seconds.

Architecture Search Performance on NAS-Bench-201

• Searching with *arch2vec* consistently outperforms other approaches on all the three datasets in NAS-Bench-201, leading to better validation and test accuracy as well as reduced variability.

Table 5: Transfer learning results on ImageNet.

Visualization of Learned Cells

- Cells with less weight-free operations (e.g. skip-connect, max-pooling) are discovered
- This is opposite to weight-sharing methods, which converge faster at the beginning but lower final accuracy

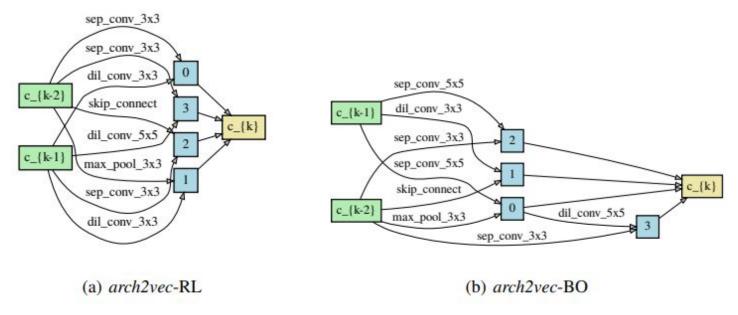

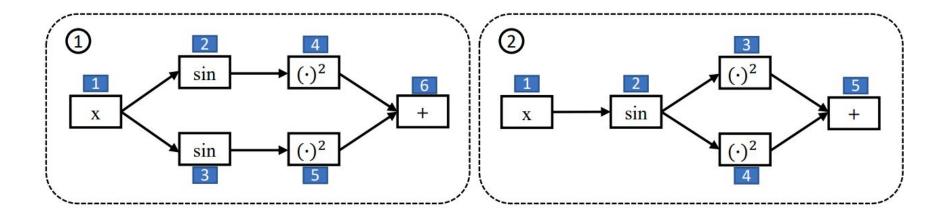

Figure 10: Best cell found by *arch2vec* using (a) RL-based and (b) BO-based search strategy.

Think about arch2vec

- Pre-training architecture representations without using their accuracies is able to better
 preserve the local structure relationship of neural architectures and helps construct a smoother
 latent space
- The pre-trained architecture embeddings considerably benefit the supervised downstream architecture search in terms of efficiency and robustness
- Think: are structure-aware architecture representations accurate enough to represent an architecture?

Drawback of Structure-aware Encoding

Two neural networks below with different structures represent the same computation: $\sin(x)^2 + \sin(x)^2$.

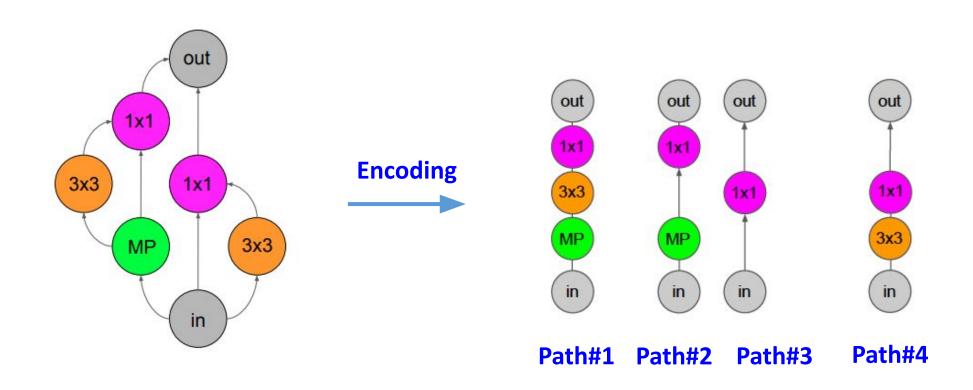

Encode structures of them will result in the same embedding located in different regions in the latent space.

Instead, encoding computation contributes to an embedding space with respect to the actual performance of the neural networks.

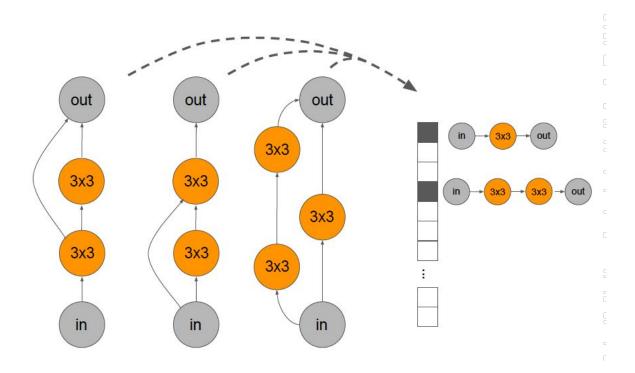

Muhan Zhang, Shali Jiang, Zhicheng Cui, Roman Garnett, Yixin Chen., D-VAE: A Variational Autoencoder for Directed Acyclic Graphs, NeurIPS 2019

Computation-aware Encoding: Path-based Encoding

Colin White, Willie Neiswanger, Sam Nolen, Yash Savani., A Study on Encodings for Neural Architecture Search, NeurIPS 2020

Computation-aware Encoding: Path-based Encoding

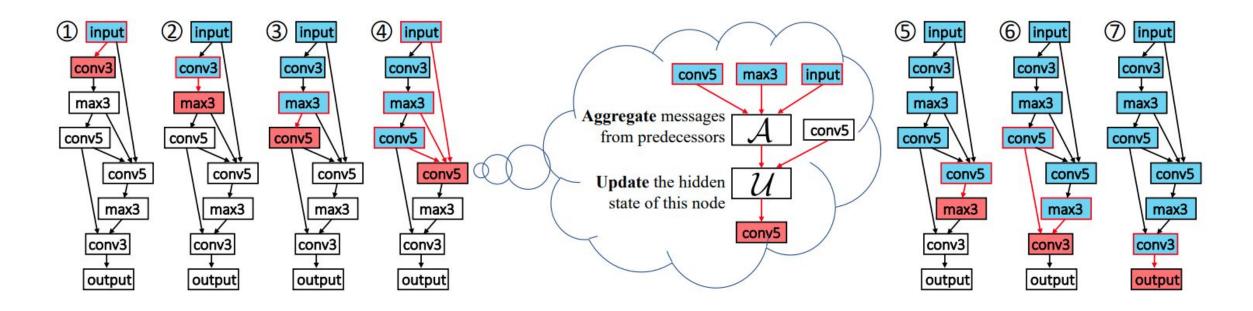

Pros

 Maps neural networks with different structures but the same computation to the same encoding.

Cons

- Scales exponentially without truncation but causes information loss with truncation.
- Shows worse generalization performance in outside search space compared to adjacency matrix-based encoding.

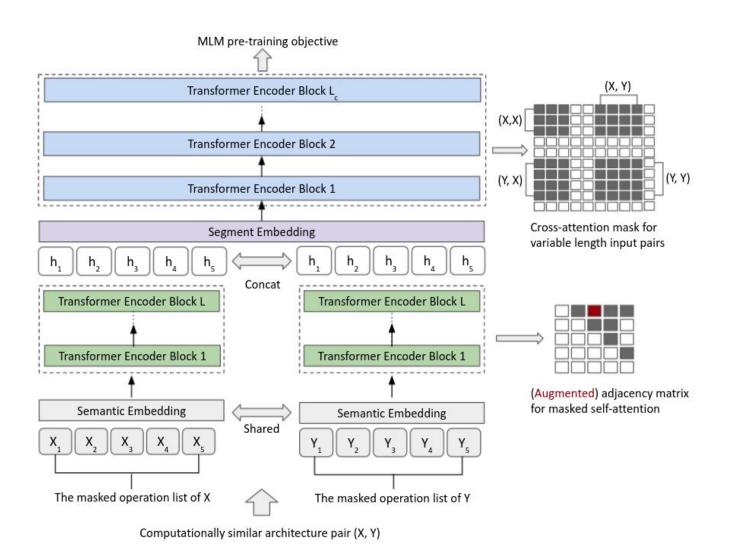

Computation-aware Encoding: D-VAE

Directly learning the generative model based on a single architecture is not trivial.

Muhan Zhang, Shali Jiang, Zhicheng Cui, Roman Garnett, Yixin Chen., D-VAE: A Variational Autoencoder for Directed Acyclic Graphs, NeurIPS 2019

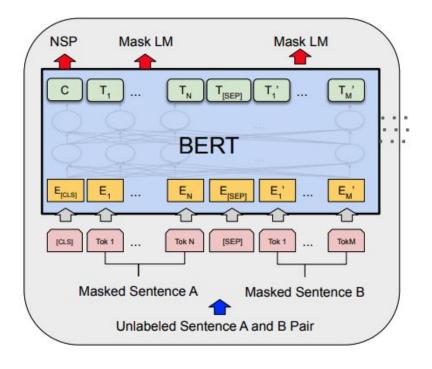

Our Proposed Method: CATE (Computation-Aware Transformer-based Encoding)

- CATE takes paired computationally similar architectures as its input.
- Similar to BERT, CATE trains a
 Transformer-based model using the masked autoencoding (MAE) objective.
- Each input architecture pair is corrupted by replacing a fraction of their operators with a special [MASK] token.
- The model is trained to predict those masked operators from the corrupted architecture pair.

Why Pairwise Pre-training

Language Modeling

Architecture Encoding

Conv 3x3 -> Conv 1x1 -> Conv 5x5 -> Conv 1x1 -> Max Pool -> ...

Conv 3x3 -> Conv 1x1 -> Conv 5x5 -> ? -> Max Pool -> ...

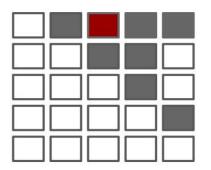

- Challenge: unlike LM, each prediction is uniformly distributed
- Solution: condition on pairwise computationally similar architectures

Jacob Devlin, Ming-Wei Chang, Kenton Lee, Kristina Toutanova. BERT: Pre-training of Deep Bidirectional Transformers for Language Understanding, NAACL-HLT 2019

Offline Architecture Pair Sampling

- Sort the architectures based on their computational attributes P (e.g. number of parameters, FLOPs).
- Use a sliding window for each architecture x_i and its neighborhood $r(x_i) = \{y : |P(x_i) P(y)| < \delta\}$, where δ is a hyperparameter for the pairwise computation constraint.
- Finally, we randomly select K distinct architectures $Y = \{y_1, \ldots, y_K\}, x_i \text{ not } \subseteq Y, Y \subseteq r(x_i) \text{ within the neighborhood to compose K architecture pairs } \{(x_i, y_1), \ldots, (x_i, y_K)\} \text{ for architecture } x_i$
- We use $\delta = 1e^6$, $2e^6$, $4e^6$, $8e^6$, K = 1, 2, 4, 8 in our experiments.

Attention Mask

(Augmented) adjacency matrix for masked self-attention

Algorithm 1 Floyd Algorithm

1: **Input:** the node set V, the adjacent matrix A

2: $\tilde{\mathbf{A}} \leftarrow \mathbf{A}$

3: for $k \in \mathcal{V}$ do

4: for $i \in \mathcal{V}$ do

5: for $j \in \mathcal{V}$ do

6: $\tilde{\mathbf{A}}_{i,j} \mid = \tilde{\mathbf{A}}_{i,k} \quad \& \quad \tilde{\mathbf{A}}_{k,j}$

7: Output: A

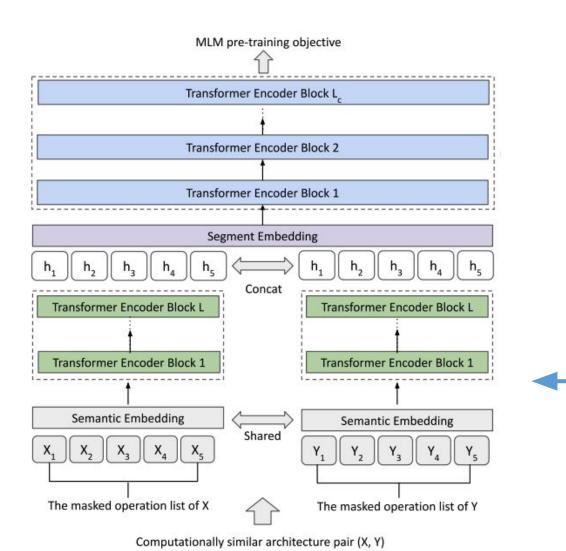

$$\mathbf{M}_{i,j}^{Direct} = \left\{ \begin{array}{ll} 0, & \text{if} \quad A_{i,j} = 1 \\ -\infty, & \text{if} \quad A_{i,j} = 0 \end{array} \right.$$

$$\mathbf{M}_{i,j}^{Indirect} = \left\{ \begin{array}{ll} 0, & \text{if} & \tilde{A}_{i,j} = 1 \\ -\infty, & \text{if} & \tilde{A}_{i,j} = 0 \end{array} \right.$$

Why:

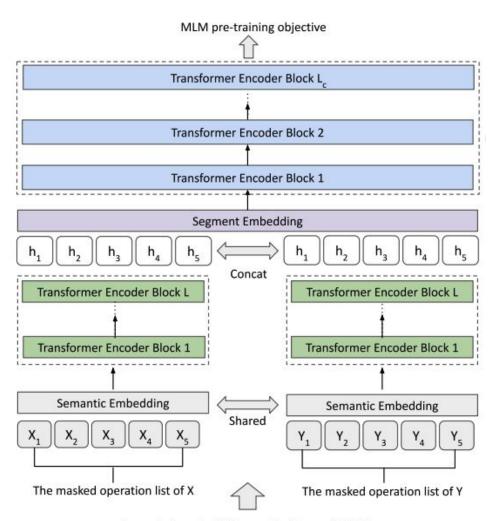

- Encode long range dependency of different operations beyond adjacency matrix
- Together with MLM, encode both local and global computation information
- Important for encodings to be generalized to outside search space beyond the training search space

Pairwise Pre-training Scheme

CATE encodes computationally similar architecture pairs through two Transformers with shared parameters.

Pairwise Pre-training Scheme

Computationally similar architecture pair (X, Y)

The two individual embeddings are then concatenated, and the concatenated embedding is fed into another Transformer with a cross-attention encoder to encode the joint information of the architecture pair.

Experimental Setup

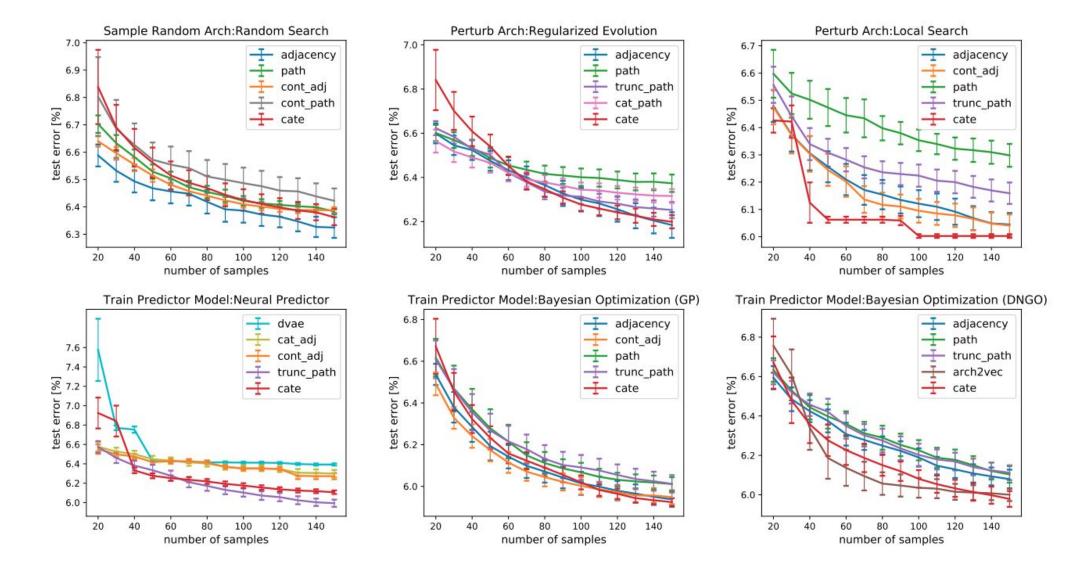

Compare CATE with 11 structure-aware and computation-aware architecture encoding schemes:

- One-hot/Categorical/Continuous adjacency matrix-based encoding (3)
- One-hot/Categorical/Continuous path-based encoding (3) and their truncated counterparts (3)
- D-VAE
- arch2vec

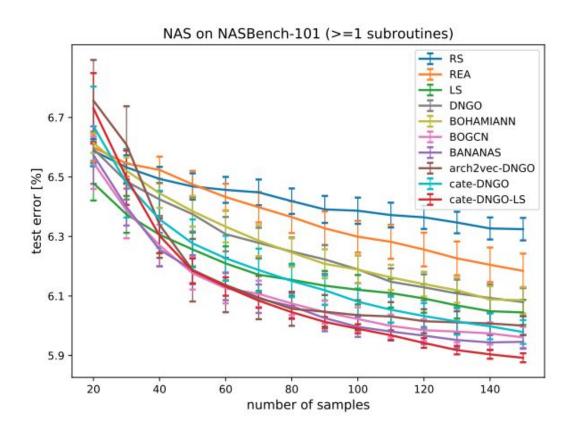

Three major encoding-dependent NAS subroutines:

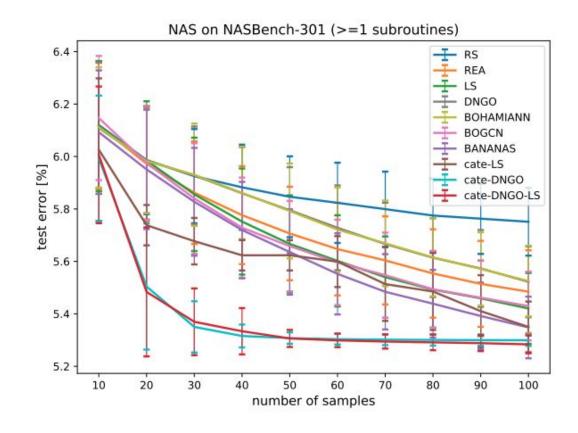

- Sample random architecture subroutine: random search (RS)
- Perturb architecture subroutine: regularized evolution (REA), local search (LS)
- Train predictor model subroutine: neural predictor, BO with GP, BO with DNGO

Comparison between CATE and other Encoding Schemes

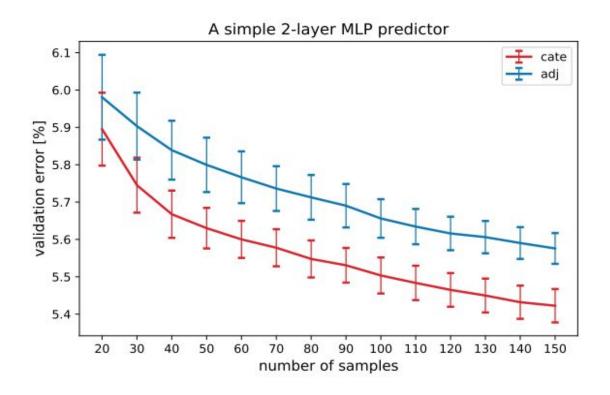

Comparison between CATE and other NAS Methods

Generalization to Outside Search Space

- The training search space is designed as a subset of NAS-Bench-101, where each included architecture has 2 to 6 nodes and 1 to 7 edges
- The test search space is disjointed from the training search space and includes architectures with 6 nodes and 7 to 9 edges.
- Better generalization when adapting to outside search space

Ablation Study

δ K	1	2	4	8
1×10^{6}	6.02	5.95	5.99	5.95
2×10^{6}	6.02	5.94	6.04	5.96
4×10^{6}	5.94	6.03	6.05	5.99
8×10^{6}	6.05	6.04	6.11	6.04

Mask type	NAS-Bench-101	NAS-Bench-301		
Direct	6.03			
Indirect	5.94	5.30		

Table 6. Direct/Indirect dependency mask selection.

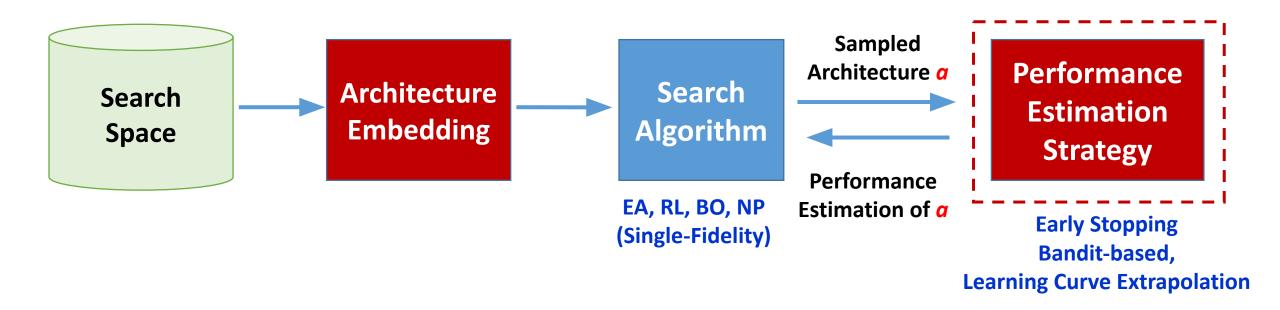

Table 4. Effects of δ and K on architecture pair sampling.

- Strong computation locality (i.e. small δ) leads to better results
- Capturing long-range dependency helps preserve computation information in the encodings

Summary

- A study on the importance of architecture representations (embeddings) on neural architecture search (NAS).
- arch2vec is an unsupervised learning-based architecture embedding method that decouples architecture representation learning and architecture search into two separate processes.
- CATE is a computation-aware architecture embedding method that encodes computations instead of structures of neural architectures via a transformer-based encoder.
- Our hope is to inspire more research on studying architecture embeddings for neural architecture search.

Recall this pipeline figure

In the following, I talk about our research on speedy performance estimation.

NAS-Bench-x11 and the Power of Learning Curves [NeurIPS' 21]

- A technique to create surrogate NAS benchmarks that include full training information for each architecture, including train/validation/test loss and accuracy learning curves
- Allow researchers to easily develop multi-fidelity NAS algorithms
- Present a simple framework for converting single-fidelity NAS to multi-fidelity NAS that allow SOTA search algorithms to achieve further improvements

Roadmap

- Generating Learning Curves
- Evaluation
- The Power of Learning Curves
- Conclusion

Generating Learning Curves

Generating realistic noise is critical

We can't just use a surrogate model to predict the entire learning curve

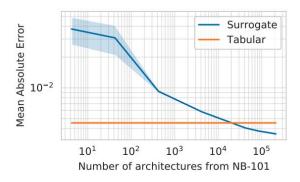

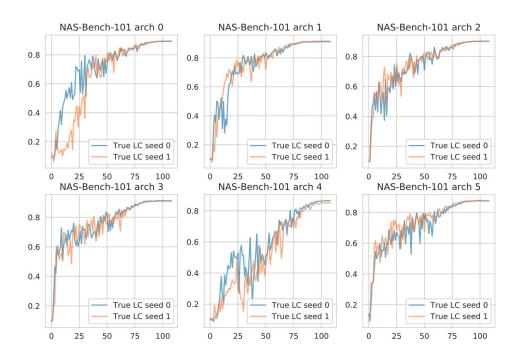

Figure 1: Number of architectures used for training the GIN surrogate model vs MAE on the NAS-Bench-101 dataset.

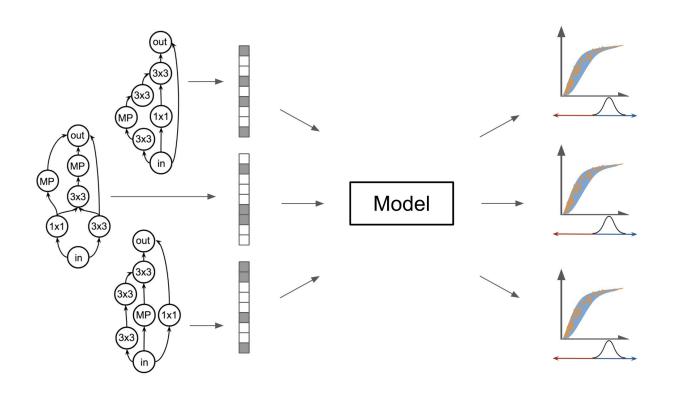

NAS-Bench-301

This would lead to de-noised learning curves

Generating Learning Curves

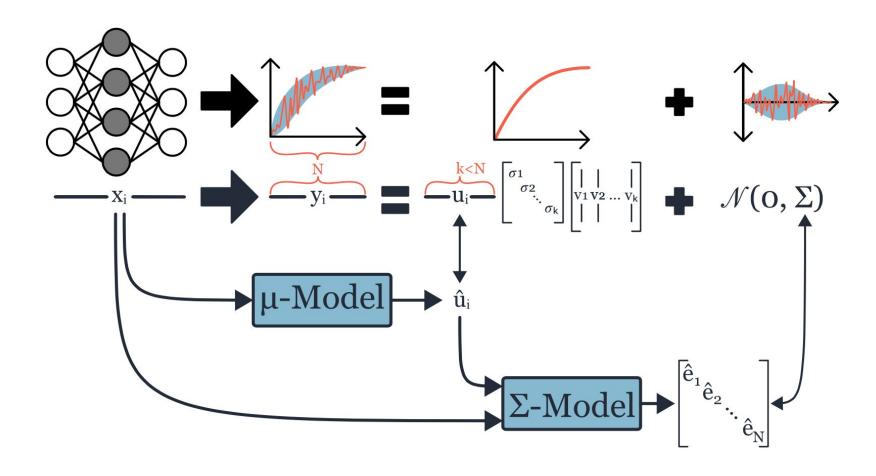

Generating realistic noise is critical

Goal: given architecture encoding, predict a distribution

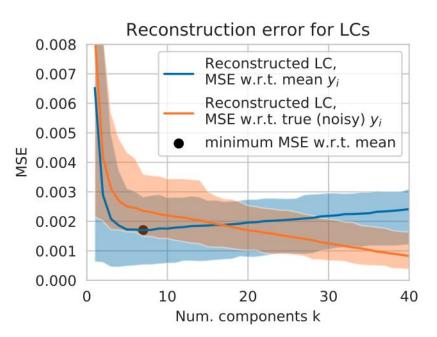

Two-part technique

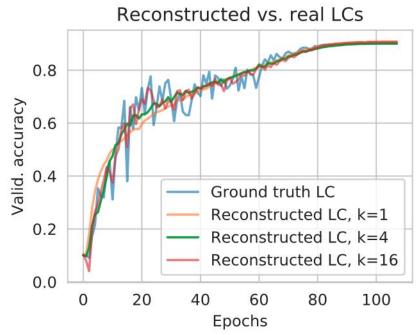

(1) Predict mean LC

(2) Predict noise

Predicting the mean learning curve

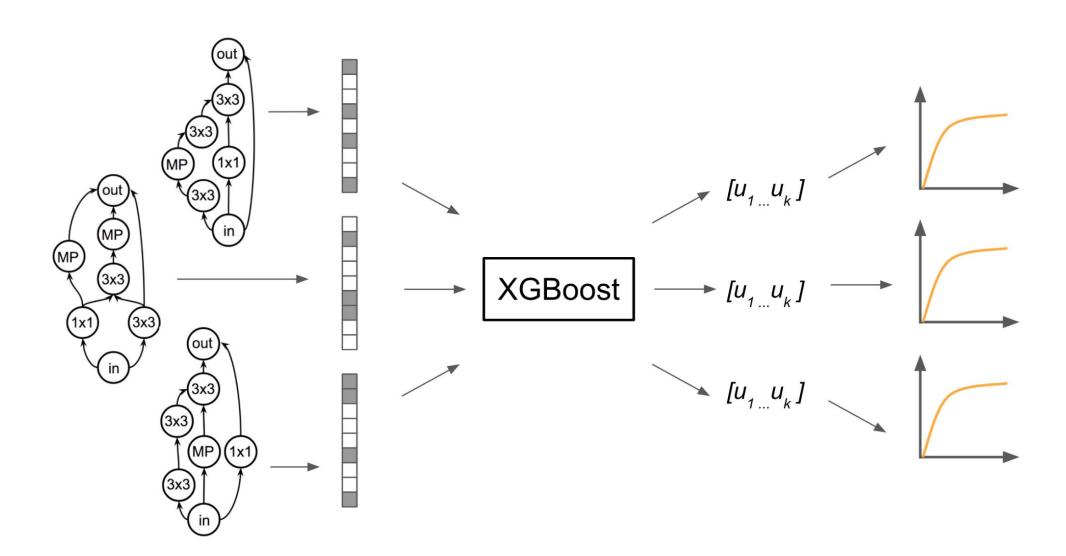

- Compress the learning curves from the training set via SVD
- 2. Predict only the top k principal components
- 3. Reconstruct via SVD statistics

- SVD helps to reduce the noise
- k=6 is the sweet spot where the compression function minimizes reconstruction error without overfitting the noise of individual learning curves

Predicting the mean learning curves

Noise Modeling

- Assume the noise comes from an isotropic Gaussian distribution
 - The noise distribution is the same for all architectures
 - a simple sample standard deviation statistic (STD)
 - a Gaussian kernel density estimation (GKDE) model trained on residuals to create a multivariate KDE
 - For each architecture, the noise in a small window of epochs are i.i.d.
 - a model trained to estimate the distribution of noise over a window of epochs

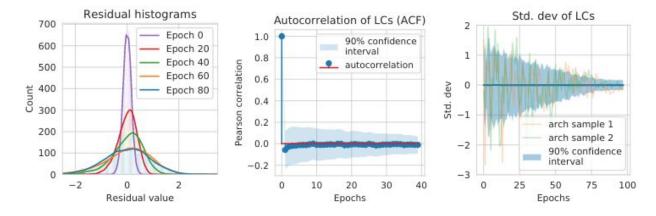

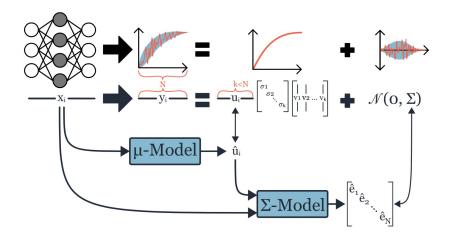

Figure 6: A plot of the residuals across all architectures for five different epochs (left). We see that the distributions are roughly Gaussian. A plot of the autocorrelation function (ACF) averaged over all training learning curves (middle). We see that there is only a small amount of autocorrelation. A plot of the 90% confidence intervals of the residuals at each epoch (right). All plots use the NAS-Bench-301 learning curve training set.

Full technique

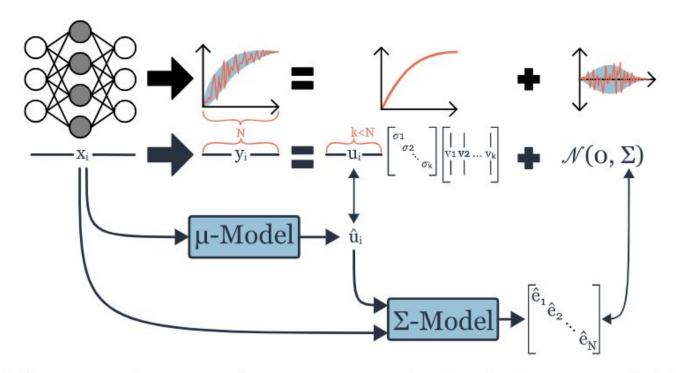

Figure 5: A summary of our approach to create surrogate benchmarks that output realistic learning curves. Compression and decompression functions are learned using the training set of learning curves (in the figure, SVD is shown, but a VAE can also be used). The compression also helps to de-noise the learning curves. A model (μ -model) is trained to predict the compressed (de-noised) learning curves given the architecture encoding. A separate model (Σ -model) is trained to predict each learning curve's noise distribution, given the architecture encoding and predicted compressed learning curve. A realistic learning curve can then be outputted by decompressing the predicted learning curve and sampling noise from the noise distribution.

Surrogate Selection

- Full ablation study on 18 combinations (SVD, VAE), (LGB, XGB, MLP), (GKDE, STD, Sliding Window)
- SVD-LGB-GKDE archives the best performance
- Therefore, we use it as the surrogate predictor to extrapolate the learning curves

Coefficient of determination: R²

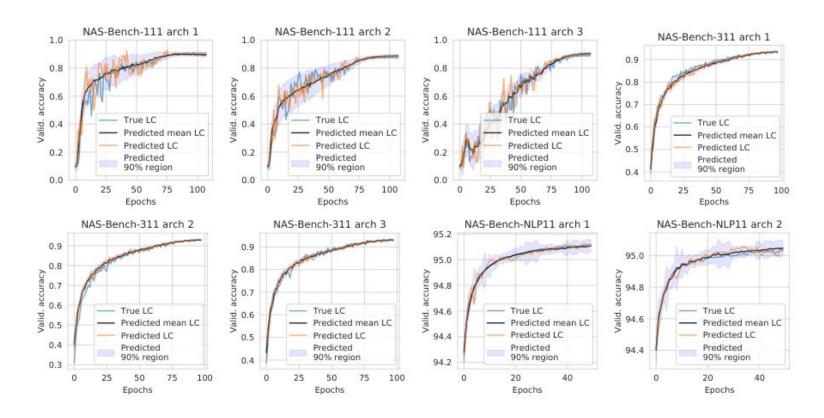

Kendall Tau rank correlation: KT

Kullback Leibler divergence: KL

Table 3: Evaluation of the surrogate benchmarks on test sets, with all combinations of models. For NAS-Bench-111 and NAS-Bench-NLP11, we use architecture accuracies as additional features to improve performance. As explained in Section B, no architectures in the NAS-Bench-NLP dataset were trained more than once, so we do not compute KL divergence for NAS-Bench-NLP11.

Generate Learning Curves

• Each image shows a true learning curve vs. a learning curve predicted by the surrogate models

The Power of Learning Curve Extrapolation

Algorithm 1 Single-Fidelity Algorithm

```
1: initialize history
2: while t < t_{\rm max}:
3: arches = gen_candidates(history)
4: accs = train(arches, epoch=E_{\rm max})
5: history.update(arches, accs)
6: Return arch with the highest acc
```

Algorithm 2 LCE Framework

```
    initialize history
    while t < t<sub>max</sub>:
    arches = gen_candidates(history)
    accs = train(arches, epoch=E<sub>few</sub>)
    sorted_by_pred = LCE(arches, accs)
    arches = sorted_by_pred[:top_n]
    accs = train(arches, epoch=E<sub>max</sub>)
    history.update(arches, accs)
    Return arch with the highest acc
```

- Propose a simple learning curve extrapolation (LCE) framework to speed-up NAS
- Extrapolator candidates:
 - Model-free:
 - Weighted Probabilistic Modeling (WPM): using MCMC to sample the most promising fit
 - Model-based:
 - Learning Curve Support vector regressor (LcSVR)

LCE Applied to a Single-Fidelity

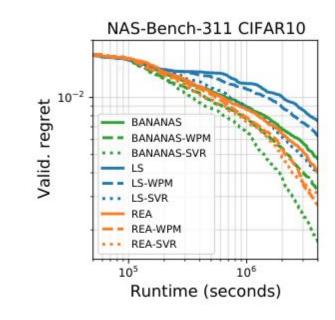

Figure 3: LCE Framework applied to single-fidelity algorithms on NAS-Bench-311.

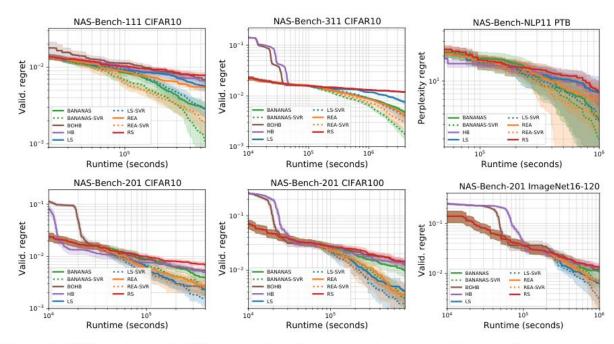

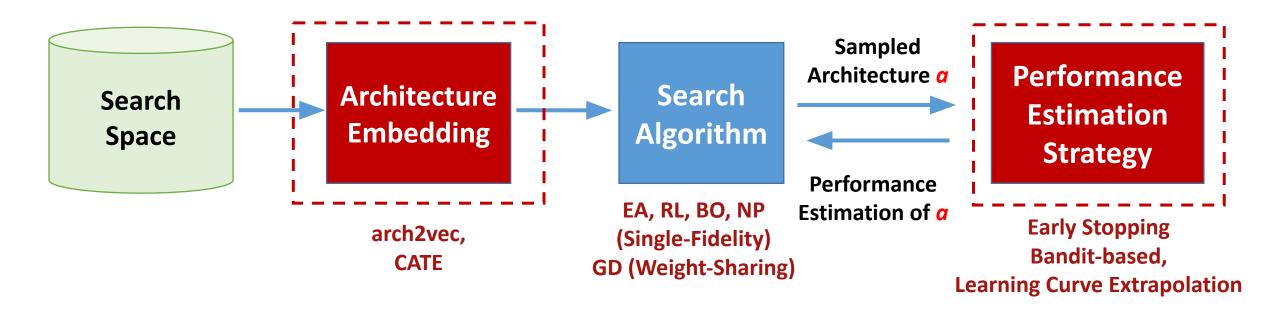

Figure 4: NAS results on six different combinations of search spaces and datasets. For every setting, an SVR augmented method performs best.

- Solid line: Best sampling-based NAS methods (e.g. BANANAS, LS, REA)
- Dashed line: Further improvement via LcSVR or WPM
- Consistent improvement across all search spaces

Summary of NB-x11

- First surrogate benchmark that outputs the full training information for each architecture
- Propose a simple LCE framework that converting single-fidelity NAS methods to multi-fidelity ones and showing that it leads to improvements over state-of-the-art NAS methods
- Future Work
 - active learning and early rejection recovery

Summary of my research
